Guideline on Thermodynamic Properties of Supercooled Water

© 2015 International Association for the Properties of Water and Steam
Publication in whole or in part is allowed in all countries provided that attribution is given to the International Association for the Properties of Water and Steam

Please cite as: International Association for the Properties of Water and Steam, Guideline on Thermodynamic Properties of Supercooled Water (2015).

This Guideline has been authorized by the International Association for the Properties of Water and Steam (IAPWS) at its meeting in Stockholm, Sweden, 28 June – 3 July, 2015. The members of IAPWS are: Britain and Ireland, Canada, the Czech Republic, Germany, Japan, Russia, Scandinavia (Denmark, Finland, Norway and Sweden), and the United States, and Associate Members Argentina and Brazil, Australia, France, Greece, New Zealand and Switzerland. The President at the time of adoption of this document is Dr. David Guzonas of Canada.

Summary
The equation of state for cold and supercooled liquid H₂O (ordinary water substance) provided in this guideline is a fundamental equation for the Gibbs energy as a function of temperature and pressure; details of the equation can be found in Ref. [1].

This guideline contains 10 pages, including this cover page.

Further information about this Guideline and other documents issued by IAPWS can be obtained from the Executive Secretary of IAPWS or from http://www.iapws.org.

1 Nomenclature

**Thermodynamic quantities**
- $c_p$: Specific isobaric heat capacity
- $c_v$: Specific isochoric heat capacity
- $g$: Specific Gibbs energy
- $p$: Pressure
- $R$: Specific gas constant
- $s$: Specific entropy
- $T$: Absolute temperature (ITS-90)
- $u$: Specific internal energy
- $v$: Specific volume
- $w$: Speed of sound
- $\alpha_p$: Thermal expansion coefficient,
  \[ \alpha_p = -(1/p)(\partial p/\partial T)_p \]
- $\kappa_T$: Isothermal compressibility,
  \[ \kappa_T = (1/p)(\partial p/\partial T)_T \]
- $\pi$: Reduced pressure, $\pi = p/(\rho_0 R T_{LL})$
- $\rho$: Mass density
- $\tau$: Reduced temperature, $\tau = (T/T_{LL}) - 1$
- $\psi$: Reduced Gibbs energy, $\psi = g/(R T_{LL})$

**Other dimensionless quantities**
- $L$: Ordering field
- $x$: Mole fraction of low-density structure
- $\phi$: Order parameter
- $\chi$: Scaling susceptibility
- $\omega$: Interaction parameter

**Subscripts**
- 0: Reference quantity
- LL: Liquid–liquid critical point
- H: Homogeneous ice nucleation limit
- t: Ice I–liquid–vapor triple point
- $\pi$: Partial derivative with respect to $\pi$
- $\tau$: Partial derivative with respect to $\tau$

**Superscripts**
- r: Regular background contribution
2 Equation of State

The equation of state presented here is in the form of the dimensionless Gibbs energy \( \psi = g/(RT_{LL}) \) as a function of temperature and pressure, corresponding to a Gibbs potential function. The expression for the Gibbs energy is based on a two-state model, in which water is considered as a mixture of a high-density structure and a low-density structure,

\[
\psi(T, P) = \psi^T(\tau, \pi) + (\tau + 1)[x L(\tau, \pi) + x \ln x + (1 - x) \ln(1 - x) + \omega(\pi)x(1 - x)],
\]

where the reduced temperature \( \tau \) and the reduced pressure \( \pi \) are defined as

\[
\tau = \frac{T}{T_{LL}} - 1, \quad \pi = \frac{p}{\rho_0 RT_{LL}}.
\]

The values of reference parameters \( T_{LL} \) and \( \rho_0 \) and the specific gas constant \( R \) are given in Table 1. The dimensionless background Gibbs energy \( \psi^T \) is given by

\[
\psi^T(\tau, \pi) = \sum_{i=1}^{20} c_i (\tau + 1)^{a_i} (\pi + \pi_0)^{b_i} e^{-d_i(\pi + \pi_0)}. \tag{3}
\]

The reference parameter \( \pi_0 \) is given in Table 1, and the coefficients \( a_i, b_i, \) and \( c_i \) are listed in Table 2. The field \( L(\tau, \pi) \) has the form

\[
L(\tau, \pi) = L_0 \frac{K_2}{2k_1k_2} \left[ 1 + k_0k_2 + k_1(\pi + k_2\tau) - K_1 \right], \tag{4}
\]

where the values of \( L_0, k_0, k_1, \) and \( k_2 \) are given in Table 1, and \( K_1 \) and \( K_2 \) are given by

\[
K_1 = \left\{ \left[ 1 + k_0k_2 + k_1(\pi - k_2\tau) \right]^2 - 4k_0k_2(\pi - k_2\tau) \right\}^{1/2},
\]

\[
K_2 = (1 + k_2^2)^{1/2}. \tag{5}
\]

The interaction parameter \( \omega \) has a linear pressure dependence,

\[
\omega(\pi) = 2 + \omega_0 \pi, \tag{6}
\]

with \( \omega_0 \) given in Table 1. The mole fraction \( x \) of the low-density structure depends on pressure and temperature, and is found by minimizing the Gibbs energy as a function of \( x \) at constant temperature and pressure,

\[
\left( \frac{\partial \psi}{\partial x} \right)_{T, P} = 0, \tag{7}
\]
which corresponds to the condition

\[ L(\tau, \pi) + \ln \frac{x}{1-x} + \omega(\pi)(1-2x) = 0. \]  \hspace{1cm} (8)

This equation cannot be solved analytically for \( x \), so the solution must be found numerically. Further information on solving this equation is given in Sec. 6.

</tbody>
</table>
The values of the coefficients $c_1$ and $c_3$ in Table 2 do not affect measurable properties of liquid water. The values of these coefficients have been chosen such that values of the specific entropy and the specific Gibbs energy at the triple point satisfy the following conditions. The zero point of the specific entropy $s$ has been chosen in accordance with the IAPWS convention that the specific entropy of liquid water is zero at the triple point,

$$s(T_t, p_t) = 0, \quad (9)$$

where $T_t$ and $p_t$ are the temperature and pressure at the ice Ih–liquid–vapor triple point [3,4],

$$T_t = 273.16 \text{ K},$$
$$p_t = 611.654771007894 \text{ Pa}. \quad (10)$$

The value for the triple-point pressure given here is not the experimental value, but was calculated [4] from the IAPWS-95 formulation and the equation of state of ice Ih. The calculated value agrees with the experimental value of $(611.657 \pm 0.010) \text{ Pa}$. In accordance with IAPWS convention, in the IAPWS-95 formulation [2] the internal energy $u$ of liquid water is set to zero at the triple point given by Eq. (10). In the present formulation, the specific internal energy of liquid water at the triple point slightly deviates from zero and it is defined by the condition that the specific Gibbs energy $g$ at the ice Ih–liquid–vapor triple point equals the specific Gibbs energy calculated from the IAPWS-95 formulation $g_{\text{IAPWS-95}}$ [2],

$$g(T_t, p_t) = u(T_t, p_t) - T_t s(T_t, p_t) + p_t v(T_t, p_t) = g_{\text{IAPWS-95}}(T_t, p_t). \quad (11)$$

By this choice, it is ensured that the temperature and pressure at the triple point computed from the present formulation for the liquid, the formulation IAPWS-95 [2] for the vapor, and the 2006 formulation for ice Ih [3], are equal to the values in Eq. (10) within the numerical precision.

### 3 Thermodynamic Properties

All thermodynamic properties can be derived from Eq. (1) by using the derivatives of the dimensionless Gibbs energy with respect to temperature and pressure. It is convenient to express the thermodynamic properties in terms of the order parameter $\phi$ and susceptibility $\chi$, defined as

$$\phi = 2x - 1, \quad \chi = \left(\frac{2}{1 - \phi^2 - \omega}\right)^{-1}. \quad (12)$$
The specific volume $v$ is given by

$$v = \frac{1}{\rho_0} \left( \frac{\tau + 1}{2} \left[ \frac{\omega_0 (1 - \phi^2)}{2} + L_\pi (\phi + 1) \right] + \psi^\tau \right),$$

(13)

and the mass density $\rho$ is found from $\rho = 1/v$. In Eq. (13) and in the following equations, subscripts $\tau$ and $\pi$ indicate partial derivatives with respect to the subscripted quantities. Expressions for the derivatives of $L$ and $\psi^\tau$ with respect to $\tau$ and $\pi$ are given in Table 3.

The specific entropy $s$ is given by

$$s = -R \left\{ \frac{(\tau + 1)L_\tau}{2} (\phi + 1) + \left[ xL + x \ln x + (1 - x) \ln(1 - x) + \omega x(1 - x) \right] + \psi^\tau \right\}.$$ 

(14)

The isothermal compressibility $\kappa_T$, thermal expansion coefficient $\alpha_p$, and specific isobaric heat capacity $c_p$ are given by

$$\kappa_T = \frac{\rho}{\rho_0^2 R T_{Ll}} \left\{ \frac{\tau + 1}{2} \left[ \chi(L_\pi - \omega, \phi)^2 - (\phi + 1)L_\pi \right] - \psi^\pi \right\},$$

$$\alpha_p = \frac{\rho}{\rho_0 T_{Ll}} \left\{ \frac{L_\pi}{2} (\tau + 1)(\phi + 1) + \frac{1}{2} \left[ \frac{\omega_0 (1 - \phi^2)}{2} + L_\pi (\phi + 1) \right] - \frac{(\tau + 1)L_\pi}{2} \chi(L_\pi - \omega, \phi) + \psi^\pi \right\},$$

$$c_p = -R \tau + 1 \left\{ L_\tau (\phi + 1) + \frac{1}{2} (\tau + 1) \left[ L_{\tau \tau} (\phi + 1) - L_\tau^2 \chi \right] + \psi^\tau \right\}.$$ 

(15)

The specific isochoric heat capacity $c_v$ is found from the thermodynamic relation

$$c_v = c_p - \frac{T \alpha_p^2}{\rho \kappa_T},$$

(16)

and the speed of sound $w$ is found from

$$w = \left( \rho \kappa_T c_v \frac{c_v}{c_p} \right)^{-1/2} = \left( \rho \kappa_T - \frac{T \alpha_p^2}{c_p} \right)^{-1/2}.$$ 

(17)
Table 3. Derivatives of $L$ and $\psi^r$

\[
\begin{array}{ll}
\text{Derivatives of } L & \text{Derivatives of } \psi^r (\text{see Note}) \\
L_\tau = \frac{L_0 K_2}{2} \left( 1 + \frac{1 - k_0 k_2 + k_1 (\pi - k_2 \tau)}{K_1} \right) & \psi^r_\tau = \sum_{i=1}^{20} c_i a_i \pi^{a_i - 1} \pi^{b_i} e^{-d_i \pi} \\
L_\pi = \frac{L_0 K_2 (K_1 + k_0 k_2 - k_1 \pi + k_1 k_2 \tau - 1)}{2 k_2 K_1} & \psi^r_\pi = \sum_{i=1}^{20} c_i a_i \pi^{a_i - 1} (b_i - d_i \pi) e^{-d_i \pi} \\
L_{\tau\tau} = -\frac{2L_0 K_2 k_0 k_1 k_2^2}{K_1^3} & \psi^r_{\tau\tau} = \sum_{i=1}^{20} c_i a_i (a_i - 1) \pi^{a_i - 2} \pi^{b_i} e^{-d_i \pi} \\
L_{\pi\pi} = \frac{2L_0 K_2 k_0 k_1 k_2}{K_1^3} & \psi^r_{\pi\pi} = \sum_{i=1}^{20} c_i a_i \pi^{a_i - 1} (b_i - d_i \pi) e^{-d_i \pi} \\
L_{\pi\tau} = -\frac{2L_0 K_2 k_0 k_1}{K_1^3} & \psi^r_{\pi\tau} = \sum_{i=1}^{20} c_i a_i \pi^{a_i - 1} b_i^2 - b_i \pi^{b_i} e^{-d_i \pi}
\end{array}
\]

Note: to simplify the expressions, the following shorthand definitions are used: $\bar{\pi} = \pi + 1$ and $\bar{\tau} = \tau + \pi_0$.

4 Range of Validity

The equation of state is recommended for the metastable liquid from the homogeneous ice nucleation temperature to the melting temperature at pressures from 0 MPa to 400 MPa. The equation is also valid for stable liquid states up to 300 K in the same pressure range, where IAPWS-95 remains the recommended formulation. In this latter region, calculated properties agree with those from IAPWS-95 within their mutual uncertainties. The equation of state behaves reasonably when extrapolated to 1000 MPa.

The homogeneous ice nucleation curve can be approximated by the fits given in Eqs. (18) and (19) [1]. There is a discontinuity in the slope of the homogeneous ice nucleation curve at approximately 181.4 K and 198.9 MPa, where Eqs. (18) and (19) intersect. Equation (18) is to be used at pressures below the discontinuity, and Eq. (19) at pressures above it.

For pressures in the range of 0 MPa to 198.9 MPa:

\[
p_{H}/\text{MPa} = 0.1 + 228.27(1 - \theta^{6.243}) + 15.724(1 - \theta^{79.81}), \quad \text{with } \theta = T/(235.15 \text{ K}). \tag{18}
\]

For pressures in the range of 198.9 MPa to 1500 MPa:

\[
T_{H}/\text{K} = 172.82 + 0.03718(p/\text{MPa}) + 3.403 \times 10^{-5}(p/\text{MPa})^2 - 1.573 \times 10^{-8}(p/\text{MPa})^3. \tag{19}
\]

Here $T_H$ and $p_H$ are the temperature and pressure on the homogeneous ice nucleation curve.
Estimates have been made of the uncertainty of the density and speed of sound when calculated from the equation of state. These estimates, shown in Figs. 1 and 2, were derived from comparisons with the various sets of experimental data.

**Fig. 1.** Uncertainties in density estimated for Eq. (1). The thin rectangles around zero pressure refer to pressures near atmospheric (0.09 MPa < \( p \) < 0.11 MPa). \( T_M \) indicates the melting temperature [5] and \( T_H \) the homogeneous nucleation temperature (Sec. 4). The melting curve does not separate uncertainty regions.

**Fig. 2.** Uncertainties in speed of sound estimated for Eq. (1). The thin rectangles around zero pressure refer to pressures near atmospheric (0.09 MPa < \( p \) < 0.11 MPa). \( T_M \) indicates the melting temperature [5]. In the region labeled “No estimate given”, there are no experimental data for the speed of sound; this region extends down to the homogeneous nucleation temperature.
6 Solving Eq. (8)

To find $x$, Eq. (8) must be solved numerically. For some implementations, it is helpful or necessary to know the interval in which the solution is located. Table 4 provides several of these intervals for $x$, depending on the values of $L$ and $\omega$.

Table 4. Intervals in which $x$, the solution of Eq. (8), is located

<table>
<thead>
<tr>
<th>Values of $L$ and $\omega$</th>
<th>Interval for $x$, containing the solution of Eq. (8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\omega &lt; (10/9) \left[ \ln(19) - L \right]$</td>
<td>0.049 - 0.5</td>
</tr>
<tr>
<td>$(10/9) \left[ \ln(19) - L \right] \leq \omega &lt; (50/49) \left[ \ln(99) - L \right]$</td>
<td>0.0099 - 0.051</td>
</tr>
<tr>
<td>$\omega \geq (50/49) \left[ \ln(99) - L \right]$</td>
<td>0.99 exp$\left[-(50/49)L - \omega\right]$ - min(1.1 exp($-L - \omega$), 0.0101) $^a$</td>
</tr>
</tbody>
</table>

$^a$ the “min” function returns the smallest of its arguments

7 Computer-Program Verification

For the verification of computer programs, Table 5 lists calculated values for several properties as well as values of $x$ and $L$. To reproduce the values in Table 5 to the number of digits given, the solution for the fraction $x$ should be accurate to $10^{-10}$.
